Linear Regression

- ► There is one scalar **target** variable *y*
- ► There is one vector **input** variable *x*
- ► Inductive bias:

$$y = \mathbf{w}^{\top} \mathbf{x}$$

Linear Regression Learning Task

Learn **w** given training examples, $\langle \mathbf{X}, \mathbf{y} \rangle$.

Chandola@UB

Geometric Interpretation

Fitting a straight line to d dimensional data

$$y = \mathbf{w}^{\top} \mathbf{x}$$

$$y = \mathbf{w}^{\top} \mathbf{x} = w_1 x_1 + w_2 x_2 + \ldots + w_d x_d$$

- ► Will pass through origin
- Add intercept

$$y = w_0 + w_1 x_1 + w_2 x_2 + \ldots + w_d x_d$$

► Equivalent to adding another column in **X** of 1s.

Matrix Calculus Basics

$$\frac{\partial \mathbf{a}^{\top} \mathbf{b}}{\partial \mathbf{a}} = \frac{\partial \mathbf{b}^{\top} \mathbf{a}}{\partial \mathbf{a}} = \mathbf{b}$$
$$\frac{\partial \mathbf{a}^{\top} \mathbf{M} \mathbf{a}}{\partial \mathbf{a}} = 2\mathbf{M} \mathbf{a}$$

where \mathbf{M} is a symmetric matrix.

Learning Parameters - Least Squares Approach

► Minimize squared loss

$$J(\mathbf{w}) = \frac{1}{2} \sum_{i=1}^{N} (y_i - \mathbf{w}^{\top} \mathbf{x}_i)^2$$

- ▶ Make prediction $(\mathbf{w}^{\top}\mathbf{x}_i)$ as close to the target (y_i) as possible
- ► Least squares estimate

$$\widehat{\boldsymbol{\mathsf{w}}} = (\boldsymbol{\mathsf{X}}^{\top}\boldsymbol{\mathsf{X}})^{-1}\boldsymbol{\mathsf{X}}^{\top}\boldsymbol{\mathsf{y}}$$

Chandola@UB

Machine Learning as Optimization Problem¹

Learning is optimization

Chandola@UR

- Faster optimization methods for faster learning
- ▶ Let $w \in \mathbb{R}^d$ and $S \subset \mathbb{R}^d$ and $f_0(w), f_1(w), \dots, f_m(w)$ be real-valued functions.
- Standard optimization formulation is:

minimize
$$f_0(w)$$

subject to $f_i(w) \le 0, i = 1, ..., m$.

¹Adapted from http://ttic.uchicago.edu/~gregory/courses/ml2012/lectures/tutorial_optimization.pdf. Also see, http://www.stanford.edu/~boyd/cvxbook/ and http://scipy-lectures.github.io/advanced/mathematical_optimization/.

Solving Optimization Problems

- Methods for general optimization problems
 - ► Simulated annealing, genetic algorithms
- Exploiting *structure* in the optimization problem
 - Convexity, Lipschitz continuity, smoothness

Convexity

Convex Optimization

Optimality Criterion

minimize
$$f_0(w)$$

subject to $f_i(w) \le 0, i = 1,..., m$.

where all $f_i(w)$ are **convex functions**.

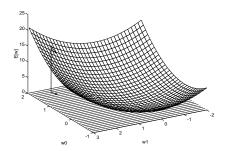

- \triangleright w_0 is feasible if $w_0 \in Dom f_0$ and all constraints are satisfied
- ▶ A feasible w^* is optimal if $f_0(w^*) \le f_0(w)$ for all w satisfying the constraints

Gradient of a Function

 Denotes the direction of steepest ascent

$$abla E(\mathbf{w}) = \left[egin{array}{c} rac{\partial E}{\partial w_0} \ rac{\partial E}{\partial w_1} \ dots \ rac{\partial E}{\partial w_d} \end{array}
ight]$$

Finding Extremes of a Single Variable Function

- Set derivative to 0
- Second derivative for minima or maxima

Finding Extremes of a Multiple Variable Function - Gradient Descent

- 1. Start from any point in variable space
- 2. Move along the direction of the steepest descent (or ascent)
 - ▶ By how much?
 - ightharpoonup A learning rate (η)
 - ▶ What is the direction of steepest descent?
 - Gradient of E at w

Training Rule for Gradient Descent

$$\mathbf{w} = \mathbf{w} - \eta \nabla E(\mathbf{w})$$

For each weight component:

$$w_j = w_j - \eta \frac{\partial E}{\partial w_j}$$

- 4 □ ▶ 4 □ ▶ 4 □ ▶ 4 □ ▶ 9 Q @

Chandola@UB CSE 474 13 / 18

Convergence Guaranteed?

- Error surface contains only one global minimum
- ► Algorithm *will* converge
 - Examples need not be linearly separable
- $ightharpoonup \eta$ should be *small enough*
- ▶ Impact of too large η ?
- ▶ Too small η ?

Issues with Gradient Descent

- ► Slow convergence
- ► Stuck in local minima

Stochastic Gradient Descent [?]

- Update weights after every training example.
- ightharpoonup For sufficiently small η , closely approximates Gradient Descent.

Gradient Descent	Stochastic Gradient Descent
Weights updated after summing er-	Weights updated after examining
ror over all examples	each example
More computations per weight up-	Significantly lesser computations
date step	
Risk of local minima	Avoids local minima

Gradient Descent Based Method

▶ Minimize the squared loss using *Gradient Descent*

$$J(\mathbf{w}) = \frac{1}{2} \sum_{i=1}^{N} (y_i - \mathbf{w}^{\top} \mathbf{x}_i)^2$$

► Why?
